Every Programming Language

Look for the following as it should almost always be there

- Comments
- Statements/Expressions
- Variable Types
- Assignment
- Basic Input/Output
- Function Declarations
- Conditionals (if-else)
- Iteration (loops)
- Aggregate data (arrays, structs, objects, etc)
- Library System
**Exercise: Traditional C Data Types**

These are the traditional data types in C

*Number of bytes for each type is NOT standard but sizes shown are common. Portable code should NOT assume any particular size which is a huge pain in the @$$.

Inspect types closely and discuss the following:

1. Ranges of integral types?  
2. Missing types you expected?  
3. void what now?  
4. How do you say char?
Answers: Traditional C Data Types

Ranges of signed integral types
Asymmetric: slightly more negative than positive

char is -128 to 127

Due to use of Two’s Complement representation, many details and alternatives later in the course.

Missing: Boolean
Every piece of data in C is either truthy or falsey:

```c
int x; scanf("%d", &x);
if(x){ printf("Truthy"); } // very common
else{ printf("Falsey"); }  
```

Typically 0 is the only thing that is falsey

Missing: String

- char holds a single character like 'A' or '5'
- No String type: arrays of char like char str[] or char *s
- char pronounced CAR / CARE like “character” (debatable)
Recall: Pointers, Addresses, Dererences

(type *ptr) **Declares** a pointer variable

*ptr **Dereferences** pointer to get/set value pointed at

```c
1 int *iptr; // Declare a pointer
2 int x = 7; // Declare/set an int
3 iptr = &x; // Set pointer
4 int y = *iptr; // Deref-ptr, gets x
5 *iptr = 9; // Deref-set ptr, changes x

6 double z = 1.23; // Declare/set double
7 double *dptr = &z; // Declare/set double ptr
8 *dptr = 4.56; // Deref-set ptr, changes z

11 printf("x: %d z: %f\n", // print via derefs
12     *iptr, *dptr);
```

Declaring pointer variables to specific types is the *normal and safest* way to write C code but can be circumvented
Exercise: Void Pointers

`void *ptr; // void pointer`

▸ Declares a pointer to something/anything
▸ Useful to store an arbitrary memory address
▸ Removes compiler’s ability to **Type Check** so introduces risks managed by the programmer

**Example:** `void_pointer.c`

▸ Predict output
▸ What looks screwy
▸ Anything look wrong?

File `void_pointer.c`:

```
1 #include <stdio.h>
2 int main(){
3    int a = 5;
4    double x = 1.2345;
5    void *ptr;
6
7    ptr = &a;
8    int b = *((int *) ptr);
9    printf("%d
",b);
10
11    ptr = &x;
12    double y = *((double *) ptr);
13    printf("%f
",y);
14
15    int c = *((int *) ptr);
16    printf("%d
",c);
17
18    return 0;
19 }```

Answers: Void Pointers

```c
#include <stdio.h>

int main()
{
    int a = 5; // int
    double x = 1.2345; // double
    void *ptr; // pointer to anything

    ptr = &a;
    int b = *((int *) ptr); // caste to convince compiler to deref
    printf("%d\n",b);

    ptr = &x;
    double y = *((double *) ptr); // caste to convince compiler to deref
    printf("%f\n",y);

    int c = *((int *) ptr); // kids: this is why types are useful
    printf("%d\n",c);
    return 0;
}
```

> gcc void_pointer.c
> ./a.out
5
1.234500
309237645  # interpreting floating point bits as an integer
### Byte-level Picture of Memory at `main()` line 20

</tbody>
</table>

- void *ptr occupies 8 contiguous bytes from #2036–#2043 and currently points at #2028; the bits/bytes ther must be caste in order to dereference.
- double x occupies 8 contiguous bytes from #2028–#2035 but ptr points to #2028 and prints bytes #2028–2031 as a 4-byte integer.
- int a occupies 4 contiguous bytes from #2024–#2027.
Answers: Void Pointers

- The big weird integer 309237645 printed at the end is because...
  - `ptr` points at a memory location with a double
  - The compiler is “tricked” into treating this location as storing int data via the `(int *)` cast
  - Integer vs Floating layout is very different, we’ll see this later
  - Compiler generates low level instructions to move 4 bytes of the double data to an integer location
  - Both size and bit layout don’t match

- Since this is possible to do on a Von Neumann machine C makes it possible

- This does not mean it is a good idea: `void_pointer.c` illustrates weird code that usually doesn’t show up

- Avoid `void *` pointers when possible, take care when you must use them (there are many times you must use them in C)
But wait, there’re more types...

## Unsigned Variants
Trade sign for larger positives

<table>

</table>
Arrays in C

- Array: a continuous block of homogeneous data
- Automatically allocated by the compiler/runtime with a **fixed size**
- Support the familiar `[ ]` syntax
- Refer to a single element via `arr[3]`
- Bare name `arr` is the **memory address** where array starts

```c
{  
  int x = 42;  
  int *p = &x;  
  int a[3] = {10,20,30};  
  int *ap = a;  
}
```

| Addr | Type | Sym | Val |
|-------|------+------+-------|
| #4948 | int* | ap | #4936 |
| #4944 | int | a[2] | 30 |
| #4940 | int | a[1] | 20 |
| #4936 | int | a[0] | 10 |
| #4928 | int* | p | #4924 |
| #4924 | int | x | 42 |

1 Modern C supports variable sized arrays in the stack but we will not use them.
### Arrays and Pointers are Related with Subtle differences

Example: `pointer_v_array.c`

```c
1 // Demonstrate equivalence of pointers and arrays
2 #include <stdio.h>
3 void print0_arr(int a[]){ // print 0th element of a
4     printf("%ld: %d\n", (long) a, a[0]); // address and 0th elem
5 }
6 void print0_ptr(int *p){ // print int pointed at by p
7     printf("%ld: %d\n", (long) p, *p); // address and 0th elem
8 }
9 int main(){
10     int *p = NULL; // declare a pointer, points nowhere
11     printf("%ld: %ld\n", (long) &p, (long)p); // by casting to 64 bit long
12     int x = 21; // declare an integer
13     p = &x; // point p at x
14     print0_arr(p); // pointer as array
15     int a[] = {5,10,15}; // declare array, auto size
16     print0_ptr(a); // array as pointer
17     //a = p; // can't change where array points
18     p = a; // point p at a
19     print0_ptr(p);
20     return 0;
21 }
```
Execution of Code/Memory 1

```c
#include <stdio.h>

void print0_arr(int a[]){
    printf("%ld: %d\n",(long) a, a[0]);
}

void print0_ptr(int *p){
    printf("%ld: %d\n",(long) p, *p);
}

int main(){
    int *p = NULL;
    printf("%ld: %ld\n", 
            (long) &p, (long)p);
    int x = 21;
    p = &x;
    print0_arr(p);
    int a[] = {5,10,15};
    print0_ptr(a);
    //a = p;
    p = a;
    print0_ptr(p); 
    return 0;
}
```

```
Summary of Pointer / Array Relationship

Arrays

- Arrays are allocated by the Compiler at a **fixed location**
- Bare name `a` references is the starting address of the array
- Must use square braces `a[i]` to index into them

Pointers

- Pointers can point to anything, can change, must be manually directed
- Can use square braces `p[i]` or deref `*p` to index into them

Interchangeability

- In most cases, functions that require an array can be passed a pointer
- Vice versa: requires a pointer can be passed an array **BECAUSE** array variables are treated as the starting memory address of the array data
Exercise: Pointer Arithmetic

“Adding” to a pointer increases the position at which it points:

▶ Add 1 to an int*: point to the next int, add 4 bytes
▶ Add 1 to a double*: point to next double, add 8 bytes

Examine `pointer_arithmetic.c` below. Show memory contents and what’s printed on the screen

```c
#include <stdio.h>

void print0_ptr(int *p){
    printf("%ld: %d\n",(long) p, *p);
}

int main(){
    int x = 21;
    int *p;
    int a[] = {5,10,15};
    p = a;
    print0_ptr(p);
    p = a+1;
    print0_ptr(p);
    p++;
    print0_ptr(p);
    p+=2;
    print0_ptr(p);
    return 0;
}
```

Pointer Arithmetic Alternatives

Pointer arithmetic often has more readable alternatives

```c
printf("enter 5 doubles\n");
double arr[5];
for(int i=0; i<5; i++){
    // POINTER: ick // PREFERRED
    scanf("%lf", arr+i); OR scanf("%lf", &arr[i]);
}
printf("you entered:\n");
for(int i=0; i<5; i++){
    // POINTER: ick // PREFERRED
    printf("%f ", *(arr+i)); OR printf("%f ",arr[i]);
}
```

But not always: following uses pointer arithmetic to append strings

```c
char name[128]; // up to 128 chars
printf("first name: ");
scanf(" %s", name); // read into name
int len = strlen(name); // compute length of string
name[len] = ' '; // replace \0 with space
printf("last name: ");
scanf(" %s",name+len+1); // read last name at offset
printf("full name: %s\n",name);
```

See read_name.c to experiment
Dynamic Memory

- Most C data has a fixed size: single vars or arrays with sizes specified at compile time
- `malloc(nbytes)` is used to manually allocate memory
  - single arg: number of bytes of memory
  - frequently used with `sizeof()` operator
  - returns a `void*` to bytes found or `NULL` if not enough space could be allocated
- `free()` is used to release memory
Exercise: Allocation Sizes

How Big
How many bytes allocated?
How many elements in the array?

char *a = malloc(16);
char *b = malloc(16*sizeof(char));
int *c = malloc(16);
int *d = malloc(16*sizeof(int));
double *e = malloc(16);
double *f = malloc(16*sizeof(double));
int **g = malloc(16);
int **h = malloc(16*sizeof(int*));

Allocate / Deallocate

▶ Want an array of ints called ages, quantity 32
▶ Want an array of doubles called dps, quantity is in variable int size
▶ Deallocate ages / dps

How many bytes CAN be allocated?
▶ Examine malloc_all_memory.c
Answers: Allocation Sizes

```c
char *a = malloc(16); // 16
char *b = malloc(16*sizeof(char)); // 16
int *c = malloc(16); // 16
int *d = malloc(16*sizeof(int)); // 64
double *e = malloc(16); // 16
double *f = malloc(16*sizeof(double)); // 128
int **g = malloc(16); // 16
int **h = malloc(16*sizeof(int*)); // 128

int *ages = malloc(sizeof(int)*32);
int size = ...;
double *dps = malloc(sizeof(double)*size);

free(ages);
free(dps);
```
When Should I `malloc()`?

**Compile Time**

- Some sizes are known at **Compile Time**
- Compiler can calculate, sizes of fixed variables, arrays, sizes of stack frames for function calls
- Most of these are automatically managed on the function call stack and don’t require an special action

**Run Time**

- Compiler can’t predict the future, at **Run Time** programs must react to
  - Typed user input like names
  - Size of a file that is to be read
  - Elements to be added to a data structure
  - Memory allocated in one function and returned to another

- As these things are determined, `malloc()` is used to allocate memory in the **heap**, when it is finished `free()` it
Common Misconception: `sizeof(thing)`

- `sizeof(thing)` determines the **Compile Time Size** of `thing`
- Useful when `malloc()`'ing stuff as in
  ```c
  int *arr = malloc(count * sizeof(int));
  ```
- **NOT USEFUL** for size of arrays/strings
  ```c
  int *arr = ...;
  int nelems = sizeof(arr);  // always 8 on 64-bit systems
  // REASON: arr is an (int *) and pointers are 8 bytes big
  ```
- To determine the size of arrays, must be given size OR have an ending sentinel value
- Strings commonly use `strlen()` to determine length:
  ```c
  char *str = "Hello world!\n";
  int len = strlen(str);  // 13
  ```
The Parts of Memory

- Running program typically has 4 regions of memory
  1. Stack: automatic, push/pop with function calls
  2. Heap: malloc() and free()
  3. Global: variables outside functions, static vars
  4. Text: Assembly instructions

- Stack grows into Heap, hitting the boundary results in stack overflow

- Will study ELF file format for storing executables

- Heap uses memory manager, will do an assignment on this
Valgrind\(^1\): Suite of tools including Memcheck

- Catches most memory errors\(^2\)
  - Use of uninitialized memory
  - Reading/writing memory after it has been free’d
  - Reading/writing off the end of malloc’d blocks
  - Memory leaks
- Source line of problem happened (but not cause)
- Super easy to use
- Slows execution of program way down

Link: Description of common Valgrind Error Messages
Exercise: `free()`'ing in the Wrong Spot

Common use for `malloc()` is for one function to allocate memory and return its location to another function (such as in A1). Question becomes when to `free()` such memory.

Program to the right is buggy, produces following output on one system

```
> gcc free_twice.c
> ./a.out
ones[0] is 0
ones[1] is 0
ones[2] is 1
ones[3] is 1
ones[4] is 1
```

▶ Why does this bug happen?
▶ How can it be fixed?
▶ Answers in `free_twice.c`
Answers: free()’ing in the Wrong Spot

- Once a malloc()’d area is free()’d, it is no longer valid
- Don’t free() data that is the return value of a function
- Never free() twice

```c
9 int *ones_array(int len){
10 int *arr = malloc(sizeof(int)*len);
11 for(int i=0; i<len; i++){
12 arr[i] = 1;
13 }
14 free(arr); // should not free an array
15 return arr; // being returned
16 }
17
18 int main(){
19 int *ones = ones_array(5);
20 for(int i=0; i<5; i++){
21 printf("ones[%d] is %d\n",i,ones[i]);
22 }
23 }
24 free(ones); // 2nd free
25 return 0;
26 }
```

Note that the Valgrind output gives an exact line number where the problem occurs but this is **not the line to change** to fix the problem.
**Answers: free()’ing in the Wrong Spot**

### Incorrect 1: Before ones_array() calls free()

**STACK**
- `main()` during line 20
- `ones_array()` before line 14
- `len` 5
- `arr` #1024

**HEAP**
- `#1040` 1
- `#1036` 1
- `#1032` 1
- `#1028` 1
- `#1024` 1
- `#1020` used block 20 bytes

### Incorrect 2: ones_array() calls free()

**STACK**
- `main()` during line 20
- `ones_array()` before line 15
- `len` 5
- `arr` #1024

**HEAP**
- `#1040` 1
- `#1036` 1
- `#1032` 1
- `#1028` This block was just free()’d available block
- `#1024` just free()’d available block
- `#1020` used block 20 bytes

### Incorrect 3: ones_array() returns free()’d array

**STACK**
- `main()` at line 21
- `ones_array()`

**HEAP**
- `#1040` 1
- `#1036` 1
- `#1032` 1
- `#1028` This block was just free()’d available block
- `#1024` just free()’d available block
- `#1020` used block 20 bytes

### Correct 1: ones_array() before return, no free()

**STACK**
- `main()` during line 20
- `ones_array()` before line 14
- `len` 5
- `arr` #1024

**HEAP**
- `#1040` 1
- `#1036` 1
- `#1032` 1
- `#1028` 1
- `#1024` 1
- `#1020` used block 20 bytes

### Correct 2: ones_array() returns valid array

**STACK**
- `main()` at line 21

**HEAP**
- `#1040` 1
- `#1036` 1
- `#1032` 1
- `#1028` 1
- `#1024` 1
- `#1020` used block 20 bytes

---

**free_twice.c Program**

**ABOVE:** Incorrect free version free()’s array before returning leading to main() getting a memory area that has no longer valid and has been marked for re-use by free().

**BELOW:** Corrected version which comments out the free() call in ones_array(); a valid memory area is returned which is printed by main() and then free()’d
structs: Heterogeneous Groupings of Data

- Arrays are homogenous: all elements the same type
- structs are C’s way of defining heterogeneous data
- Each field can be a different kind
- One instance of a struct has all fields
- Access elements with 'dot' notation
- Several syntaxes to declare, we’ll favor modern approach
- Convention: types have _t at the end of their name to help identify them (not a rule but a good idea)

```c
typedef struct{ // declare type
    int an_int;
    double a_doub;
    char the_car;
    int my_arr[6];
} thing_t;

thing_t a_thing; // variable
a_thing.an_int = 5;
a_thing.a_doub = 9.2;
a_thing.the_car = 'c';
a_thing.my_arr[2] = 7;
int i = a_thing.an_int;

thing_t b_thing = { // variable
    .an_int = 15,    // initialize
    .a_doub = 19.2,  // all fields
    .the_car = 'D',
    .my_arr = {17, 27, 37,
               47, 57, 67}
};
```
### Recursive Types

- structs can have pointers to their same kind
- Syntax is a little wonky

```c
typedef struct node_struct {
    char data[128];
    struct node_struct *next;
} node_t;
```

### Arrow Operator

- Pointer to struct, want to work with a field
- Use 'arrow' operator -> for this (dash/greater than)

```c
node_t *one_node = malloc(sizeof(node_t));
int length = 5;
node_t *node_arr = malloc(sizeof(node_t) * length);
node_t *node = ...;
if(node->next == NULL){ ... }
list_t *list = ...;
list->size = 5;
list->size++;
```

### Dynamically Allocated Structs

- Dynamic Allocation of structs requires size calculation
- Use sizeof() operator

```c
node_t *one_node =
    malloc(sizeof(node_t));
int length = 5;
node_t *node_arr =
    malloc(sizeof(node_t) * length);
node_t *node = ...;
if(node->next == NULL){ ... }
list_t *list = ...;
list->size = 5;
list->size++;
```
Exercise: Structs in Memory

- Structs allocated in memory are laid out compactly
- Compiler may *pad* fields to place them at nice alignments (even addresses or word boundaries)

```c
typedef struct {
  double x;
  int y;
  char nm[4];
} small_t;

int main(){
  small_t a = {.x=1.23, .y=4, .nm="hi"};
  small_t b = {.x=5.67, .y=8, .nm="bye"};
}
```

<table>
<thead>
<tr>
<th>Addr</th>
<th>Type</th>
<th>Sym</th>
<th>Val</th>
</tr>
</thead>
<tbody>
<tr>
<td>#1000</td>
<td>double</td>
<td>a.x</td>
<td>1.23</td>
</tr>
<tr>
<td>#1008</td>
<td>int</td>
<td>a.y</td>
<td>4</td>
</tr>
<tr>
<td>#1012</td>
<td>char</td>
<td>a.nm[1]</td>
<td>h</td>
</tr>
<tr>
<td>#1013</td>
<td>char</td>
<td>a.nm[1]</td>
<td>i</td>
</tr>
<tr>
<td>#1014</td>
<td>char</td>
<td>a.nm[2]</td>
<td>\0</td>
</tr>
<tr>
<td>#1015</td>
<td>char</td>
<td>a.nm[3]</td>
<td>?</td>
</tr>
<tr>
<td>#1016</td>
<td>double</td>
<td>b.x</td>
<td>5.67</td>
</tr>
<tr>
<td>#1024</td>
<td>int</td>
<td>b.y</td>
<td>8</td>
</tr>
<tr>
<td>#1028</td>
<td>char</td>
<td>b.nm[0]</td>
<td>b</td>
</tr>
<tr>
<td>#1029</td>
<td>char</td>
<td>b.nm[1]</td>
<td>y</td>
</tr>
<tr>
<td>#1030</td>
<td>char</td>
<td>b.nm[2]</td>
<td>e</td>
</tr>
<tr>
<td>#1031</td>
<td>char</td>
<td>b.nm[3]</td>
<td>\0</td>
</tr>
</tbody>
</table>

Result of?

```c
scanf("%d", &a.y); // input 7  
scanf("%lf", &b.x); // input 9.4  
scanf("%s", b.nm); // input yo
```
Answers: Structs in Memory

```c
scanf("%d", &a.y); // input 7
scanf("%lf", &b.x); // input 9.4
scanf("%s", b.nm); // input yo
```

<table>
<thead>
<tr>
<th>Addr</th>
<th>Type</th>
<th>Sym</th>
<th>Before</th>
<th>After</th>
</tr>
</thead>
<tbody>
<tr>
<td>#1031</td>

<td>4</td>
<td>7</td>
</tr>
<tr>
<td>#1000</td>
<td>double</td>
<td>a.x</td>
<td>1.23</td>
<td></td>
</tr>
</tbody>
</table>
Newcomers wonder when to use Dots vs Arrows

- Use Dot (s.field) with an **Actual** struct
- Use Arrow (p->field) for a **Pointer** to a struct

```c
small_t small; // struct: 16 bytes
small_t *sptr; // pointer: 8 bytes

sptr = &small; // point at struct
small.x = 1.23; // actual struct
sptr->x = 4.56; // through pointer
(*sptr).x = 4.56; // ICK: not preferred
small.y = 7;  // actual struct
sptr->y = 11; // through pointer
small.nm[0] = 'A'; // through struct
sptr->nm[1] = 'B'; // through pointer
sptr->nm[2] = '\0'; // through pointer
```

Memory at end of code on left

<table>
<thead>
<tr>
<th>Addr</th>
<th>Sym</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>#2072</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>#2064</td>
<td>sptr</td>
<td>#2048</td>
</tr>
<tr>
<td>#2063</td>
<td>small.nm[3]</td>
<td>?</td>
</tr>
<tr>
<td>#2062</td>
<td>small.nm[2]</td>
<td>\0</td>
</tr>
<tr>
<td>#2061</td>
<td>small.nm[1]</td>
<td>B</td>
</tr>
<tr>
<td>#2060</td>
<td>small.nm[0]</td>
<td>A</td>
</tr>
<tr>
<td>#2056</td>
<td>small.y</td>
<td>11</td>
</tr>
<tr>
<td>#2048</td>
<td>small.x</td>
<td>4.56</td>
</tr>
</tbody>
</table>
```
// Demonstrate use of pointers, malloc() with structs, scanning
// structs fields

#include <stdlib.h>
#include <stdio.h>

typedef struct { // simple struct
double x; int y; char nm[4]; } small_t;

int main(){
  small_t c; // stack variable
  small_t *cp = &c; // address of stack var
  scanf("%lf %d %s", &cp->x, &cp->y, cp->nm); // read struct fields
  printf("%f %d %s
",cp->x, cp->y, cp->nm); // print struct fields

  small_t *sp = malloc(sizeof(small_t)); // malloc'd struct
  scanf("%lf %d %s", &sp->x, &sp->y, sp->nm); // read struct fields
  printf("%f %d %s
",sp->x, sp->y, sp->nm); // print struct fields

  small_t *sarr = malloc(5*sizeof(small_t)); // malloc'd struct array
  for(int i=0; i<5; i++){
    scanf("%lf %d %s", &sarr[i].x, &sarr[i].y, sarr[i].nm); // read
    printf("%f %d %s
", sarr[i].x, sarr[i].y, sarr[i].nm); // print
  }

  free(sp); // free single struct
  free(sarr); // free struct array
  return 0;
}
File Input and Output

- Standard C I/O functions for reading/writing file data.
- Work with text data: formatted for human reading

```c
FILE *fopen(char *fname, char *mode);
// open file named fname, mode is "r" for reading, "w" for writing
// returns a File Handle (FILE *) on success
// returns NULL if not able to open file; do not fclose(NULL)
```

```c
int fclose(FILE *fh);
// close file associated with fh, writes pending data to file,
// free()'s memory associated with open file
// Do not fclose(NULL)
```

```c
int fscanf(FILE *fh, char *format, addr1, addr2, ...);
// read data from an open file handle according to format string
// storing parsed tokens in given addresses returns EOF if end of file
// is reached
```

```c
int fprintf(FILE *fh, char *format, arg1, arg2, ...);
// prints data to an open file handle according to the format string
// and provided arguments
```

```c
void rewind(FILE *fh);
// return the given open file handle to the beginning of the file.
```

Example of use in struct_text_io.c
Binary Data I/O Functions

- Open/close files same way with `fopen()`/`fclose()`
- Read/write raw bytes (not formatted) with the following

```c
size_t fread(void *dest, size_t byte_size, size_t count, FILE *fh);
// read binary data from an open file handle. Attempt to read
// byte_size*count bytes into the buffer pointed to by dest.
// Returns number of bytes that were actually read

size_t fwrite(void *src, size_t byte_size, size_t count, FILE *fh);
// write binary data to an open file handle. Attempt to write
// byte_size*count bytes from buffer pointed to by src.
// Returns number of bytes that were actually written
```

See examples of use in `struct_binary_io.c`

Tradeoffs between Binary and Textual Files

- Binary files usually smaller than text and can be directly read into memory but NOT easy on the eyes
- Text data more readable but more verbose, must be parsed and converted to binary numbers
Strings are Character Arrays

Conventions

- Convention in C is to use character arrays as strings
- Terminate character arrays with the \0 null character to indicate their end

```c
char str1[6] = {'C','h','r','i','s','\0'};
```

- Null termination done by compiler for string constants

```c
char str2[6] = "Chris";
// is null terminated
```

- Null termination done by most standard library functions like `scanf()`

Be aware

- `fread()` does not append nulls when reading binary data
- Manually manipulating a character array may overwrite ending null

String Library

- Include with `<string.h>`
- Null termination expected
- `strlen(s)`: length of string
- `strcpy(dest, src)`: copy chars from `src` to `dest`
- Limited number of others
Exercise: Common C operators

Arithmetic  +  -  *  /  %
Comparison  ==  >  <  <=  >=  !=
Logical    &&   ||    !
Memory     &   and   *
Compound   +=  -=  *=  /=  ...
Bitwise Ops  ^  |  &  ~
Conditional  ?  :

Bitwise Ops
Will discuss soon

int x = y << 3;
int z = w & t;
long r = x | z;

Integer/Floating Division
Predict values for each variable

int q = 9 / 4;
int r = 9 % 4;
double x = 9 / 4;
double y = (double) 9 / 4;
double z = ((double)9) / 4;
double w = 9.0 / 4;
double t = 9 / 4.0;
int a=9, b=4;
double t = a / b;

Conditional (ternary) Operator

double x = 9.95;
int y = (x < 10.0) ? 2 : 4;
**Answers: Integer vs Floating Division**

Integer versus real division: **values** for each of these are...

```java
int q = 9 / 4; // quotient 2
int r = 9 % 4; // remainder 1
double x = 9 / 4; // 2.0 (int quotient first)
double y = (double) 9 / 4; // 2.25
double z = ((double)9) / 4; // 2.25
double w = 9.0 / 4; // 2.25
double t = 9 / 4.0; // 2.25
int a=9, b=4;
double t = a / b; // 2 (int quotient)
```
C Control Structures

Looping/Iteration

// while loop
while(truthy){
    stuff;
    more stuff;
}

// for loop
for(init; truthy; update){
    stuff;
    more stuff;
}

// do-while loop
do{
    stuff;
    more stuff;
} while( truthy );

Conditionals

// simple if
if( truthy ){
    stuff;
    more stuff;
}

// chained exclusive if/elses
if( truthy ){
    stuff;
    more stuff;
}
else if(other){
    stuff;
}
else{
    stuff;
    more stuff;
}

// ternary ? : operator
int x = (truthy) ? yes : no;
Jumping Around in Loops

break: often useful

// break statement ends loop
// only valid in a loop
while(truthy){
    stuff;
    if( istrue ){
        something;
        break;-----+
    } |
    more stuff; |
} |
after loop; <---+

// break ends inner loop,
// outer loop advances
for(int i=0; i<10; i++){
    for(int j=0; j<20; j++){
        printf("%d %d ",i,j);
        if(j == 7){
            break;------+
        } |
    } |
}
printf("\n");<--+

continue: occasionally useful

// continue advances loop iteration
// does update in for loops

for(int i=0; i<10; i++){ |
    printf("i is %d\n",i); |
    if(i % 3 == 0){ |
        continue;----------+
    }
    printf("not div 3\n"); |
}

Prints
i is 0
i is 1
not div 3
i is 2
not div 3
i is 3
i is 4
not div 3
...
Really Jumping Around: goto

- Machine-level control involves jumping to different instructions
- C exposes this as
  - somewhere: label for code position
  - goto somewhere; jump to that location
- goto_demo.c demonstrates a loop with gotos
- Avoid goto unless you have a compelling motive
- Beware spaghetti code...

```
1 // Demonstrate control flow with goto
2 // Low level assembly jumps are similar
3 #include <stdio.h>
4 int main(){
5   int i=0;
6   beginning:   // a label for gotos
7       printf("i is %d\n",i);
8       i++;
9       if(i < 10){
10          goto beginning; // go back
11         }
12     goto ending;       // go forward
13     printf("print me please!\n");
14     ending:            // label for goto
15     printf("i ends at %d\n",i);
16     return 0;
17 }
```

XKCD #292
switch() / case: the **worst** control structure

- switch/case allows jumps based on an integral value
- Frequent source of errors
- switch_demo.c shows some features
  - use of break
  - fall through cases
  - default catch-all
  - Use in a loop
- May enable some small compiler optimizations
- Almost **never** worth correctness risks: one good use in my experience
- Favor if/else if/else unless compelled otherwise

```
1  // Demonstrate peculiarities of switch/case
2  #include <stdio.h>
3  int main(){
4    while(1){
5      printf("enter a char: ");
6      char c;
7      scanf(" %c",&c); // ignore preceding spaces
8      switch(c){ // switch on read char
9        case 'j': // entered j
10           printf("Down line
");
11           break; // go to end of switch
12        case 'a': // entered a
13           printf("little a
");
14           break; // go to end of switch
15        case 'A': // entered A
16           printf("big A
");
17           printf("append mode\n");
18           break; // go to end of switch
19        case 'q': // entered q
20           printf("Quitting\n");
21           return 0; // return from main
22        default: // entered anything else
23           printf("other '%c'\n",c);
24           break; // go to end of switch
25         }
26     }
27  return 0;
28 }```

A Program is Born: Compile, Assemble, Link, Load

- Write some C code in `program.c`
- Compile it with toolchain like GNU Compiler Collection
  
  `gcc -o program prog.c`
- Compilation is a multi-step process
  - Check syntax for correctness/errors
  - Perform optimizations on the code if possible
  - Translate result to **Assembly Language** for a specific target processor (Intel, ARM, Motorola)
  - **Assemble** the code into **object code**, binary format (ELF) which the target CPU understands
  - **Link** the binary code to any required libraries (e.g. printing) to make an **executable**
- Result: executable program, but...
- To run it requires a **loader**: program which copies executable into memory, initializes any shared library/memory references required parts, sets up memory to refer to initial instruction
Review Exercise: Memory Review

1. How do you allocate memory on the Stack? How do you de-allocate it?
2. How do you allocate memory dynamically (on the Heap)? How do you de-allocate it?
3. What other parts of memory are there in programs?
4. How do you declare an array of 8 integers in C? How big is it and what part of memory is it in?
5. Describe several ways arrays and pointers are similar.
6. Describe several ways arrays and pointers are different.
7. Describe how the following two arithmetic expressions differ.
   ```c
   int x=9, y=20;
   int *p = &x;
   x = x+1;
   p = p+1;
   ```
Answers: Memory Review

1. How do you allocate memory on the Stack? How do you de-allocate it?
   Declare local variables in a function and call the function. Stack frame has memory for all locals and is de-allocated when the function finishes/returns.

2. How do you allocate memory on the Heap? How do you de-allocate it?
   Make a call to ptr = malloc(nbytes) which returns a pointer to the requested number of bytes. Call free(ptr) to de-allocate that memory.

3. What other parts of memory are there in programs?
   Global area of memory has constants and global variables. Text area has binary assembly code for CPU instructions.

4. How do you declare an array of 8 integers in C? How big is it and what part of memory is it in?
   An array of 8 ints will be 32 bytes big (usually).
   On the stack: int arr[8]; De-allocated when function returns.
   On the heap: int *arr = malloc(sizeof(int) * 8); Deallocated with free(arr);
5. Describe several ways arrays and pointers are similar.
   Both usually encoded as an address, can contain 1 or more items, may use square brace indexing like arr[3] = 17; Interchangeable as arguments to functions. Neither tracks size of memory area referenced.

6. Describe several ways arrays and pointers are different.
   Pointers may be deref’d with *ptr; can’t do it with arrays. Can change where pointers point, not arrays. Arrays will be on the Stack or in Global Memory, pointers may also refer to the Heap.

7. Describe how the following two arithmetic expressions differ.

```c
int x=9, y=20; // x at #1024
int *p = &x; // p hold VALUE #1024 (points at x)
x = x+1; // x is now 10: normal arithmetic
p = p+1; // p is now #1028: pointer arithmetic
// may or may not point at y
```
